Research and Education

Medical Informatics and Telemedicine at the Politecnico di Milano

Abstract: Research and training programs in Medical Informatics and Telemedicine offered at the Politecnico di Milano are summarized. The educational pathways refer to the programs of: the (5-years) Laurea Degree, the (3-years) Diploma Universitario Degree, the post-Laurea (3-years) Doctoral Degree, the (1-year) Master's Degree, and a Continuing Education Program. The research programs focus on databases and extend to optimization of the “Visible Human Dataset-Milano Mirror Site” services. Additional activities relate to standardization at both the Italian and European levels, and to cooperation with hospitals and manufacturers.

Keywords: Education, Databases, Visible Humans

1. Framework

One generation ago, at the beginning of the 1970s, we were a small group of enthusiastic and idealistic young persons, fascinated by the ideas of the “mission” of Biomedical Engineering for the benefit of mankind. Since that time, we have always been too many persons in relation to the number of academic positions available: this remains true today. This was also evident in the Academic Year 1997/98, when we gave the opening address to the 236 freshmen enrolled for the five-year Laurea Degree in Biomedical Engineering. However, despite having been - academically - too many at one time, we believe that we are still too few in relation to the need of our skills in Italy today. This is probably the fuel that maintains our enthusiasm, one generation later. According to the ideas and the behavioral styles generated by our father in science, Emanuele Biondi (still active and creative today) and according to our sometimes conflicting scientific beliefs, we forged the Department of Biomedical Engineering of the Politecnico di Milano. One can find us at http://www.biomed.polimi.it. The Department, founded in 1990 and now chaired by Antonio Pedotti, is also the main academic focus for the educational and research activities offered by the Politecnico di Milano in the field of Medical Informatics and Telemedicine (also described at website http://www.medinfopoli.polimi.it).

2. The Educational Activities

The inherent aim in each educational program offered in Medical Informatics and Telemedicine at the Politecnico di Milano is to enable students to acquire technical skills in order to become information and communication technology experts, in whom the physician believes. Many educators know how difficult it is to achieve such an aim, but there are no alternatives. This has been proven by the history of technology in medicine. A target such as this requires that students personally acquire some fundamental roots of knowledge. The first root relates to the problems in the fields of Medicine and Health Care. The knowledge should be deep, even though the educational traditions may be young. It should avoid excessive hope in the ability of the physician, as the client of the products developed for him, to provide a detailed list of the activities required to solve his problems. The second root of knowledge required relates to Information and Communication Technology tools. Methods, techniques, devices and systems, suitable for implementing the solutions for the problems present in Medicine and Health Care, should be carefully selected.

The envisaged working relation foresees two interactive but separate roles. The physician plays the customer role: he asks for solutions, and evaluates their implementation. The medical informatician plays the provider role: he has to develop the solutions. The overall relation will probably lead to a permanent conflict and interactive negotiation between the two roles. Nevertheless, they have to share the posi...
tive final aim of the conflict, i.e. the
development of solutions for the ben­
efit of patients. Evolution brings addi­
tional difficulties. We refer to the ev­
olution of the needs of Medicine and
Health Care on the one side, to the
very fast evolution of Information and
Communication Technology tools on
the other side, and to the fact that
neither may be well aligned to the
needs of Medicine. For the Medical
Informatician to remain in good dia­
logue and collaboration with the physi­
cian is a difficult but necessary task.
The different educational curricula and
post-degree programs offered at the
Politecnico di Milano are devised to
fulfil this aim.

2.1 The Laurea Degree

At this level, the concept of “medical
information and communication
technology, reliable interlocutor for
the client physician (MICTRID)” im­
plies that the medical informatician will
cooperate with physicians at top ma­
angement levels. Examples of typical
activities are the choice of new trends
in hospital information systems (will we
go with Java?), and the tools for
achieving data security and privacy
(does PCASSO make sense for us?),
etc. Professional roles such as junior
advisor, senior programmer and sys­
tems manager are targets within the
MICTRID concept.

The announcement of the 1996/97
first-semester edition of the course on
Medical Informatics is mentioned in
Table 1. The course is now offered to
students of the five-year “Laurea”
degrees in Biomedical Engineering,
Computer Engineering, Electronic En­
gineering and Mechanical Engineer­
ing. Prerequisites for admission are
two basic courses in computer pro­
gramming, taken in the first and sec­
ond year of the “Laurea” degrees.
Additional information on teaching and
research activities at the Laboratory
of Medical Informatics is available at
polimi.it. In addition, for 1997/98, a
“learning by doing” project, will be
developed (at an Internet-connected
classroom), entitled “Internet for Med­i­
cine and Health Care”. Its final pro­
ducts will be available as MedInfoPoli'98
on CD/WEB.

2.2 The Diploma Universitario
Degree

At this level, the MICTRID concept
will involve cooperation between the
medical informatician and physicians
at the daily practice levels. Examples
of typical activities are the optimal
maintenance of systems and devices, 
minor additional customization imple­
mentations, new releases, customer
support, etc. Professional roles such
as junior programmer, product man­
ger, systems administrator are tar­
gets within the MICTRID concept.

Within the framework of the Di­
ploma Universitario Degree in Bio­
medical Engineering, the Medical
Informatics course is compulsory for
all students in their third and final year
of attendance. It comes after the single
course in Basic Computer Program­
ing taken in their first year. The
addition of a second course in the field,
to be taken before Medical Informatics,
would be welcome; however, the large
number of subjects given to the stu­
dents has precluded this up to now.
The establishment of a “Hospital In­
formation Systems” module within the
program is now under evaluation. This
could be an effective solution for deliv­
ering the necessary concepts to the
students. Additional information on the
Diploma Universitario Degree in Bio­
medical Engineering is available at
http://www.biomed.polimi.it.

2.3 The Post-Graduate Master's
Program in Telemedicine

The typical activities within the
MITRID concept outlined for the
Laurea Degree level are also valid for
this postgraduate one-year program.
The target audience, however, is mainly
those Laurea who graduated in En­
gineering but did not take courses in
Medical Informatics and Biomedical
Engineering, and those Laurea who
graduated in Medical Sciences, Phar­
maceutical Sciences and, Biologic­
Sciences, who did not take courses in
Information and Communication Tech­
nology. Professional roles such as jun­
or advisor, senior programmer, sys­
tems manager, professional advise­
d, are within the MICTRID concept.

The 1997/98 edition of the Master's
Program in Telemedicine is open to 15
candidates. Entirely sponsored this year
by the Lombardia Region local gov­
erments, the Master’s Program in
Telemedicine comes from the
Dipartimento di Bioingegneria and the
Cefriel Consortium. Among the sev­
eral consortia managed by the
Politecnico di Milano, the Cefriel Con­
sortium has offered a Master’s course
in Information Technology for the last
10 years. Additional information is
available at the web site of the Cefriel

2.4 The Post-Graduate Doctoral
Program in Bioengineering

At this level, the MICTRID concept
focuses on specific research sub­
jects. Examples of activities are model­
ing and implementing users views by
object-oriented approaches, applying
object-oriented technologies in model­
ling and querying temporally-oriented cli­
dical databases, etc. These students in­
teract with physicians involved in re­
search and submit results for publica­
tion in renowned scientific journals.
Professional roles such as proj­
ector, scientific advisors, researchers,
are targets within the MICTRID con­
cept.

2.5 The Continuing Education
Program

The Engineering Faculty of the
Politecnico di Milano offers a Conti­
nuing Education Program which consis­
t of some 50 courses (of varying dur­
covering many of the engineering disciplines. The program, recently renamed “Poliedra”, is described at http://www.polimi.it. For Medical Informatics and Telemedicine, the topic “Internet for Medicine and Health Care” is offered as a short laboratory course, inspired by the concept of “learning by doing”.

At this level, the MICTRID concept involves cooperation between the medical informatician (frequently already working at an institution), and the institution’s physicians and managers for rapid application of the benefits of some services available via Internet. Examples of typical activities are use of web addresses in relation to medical publishers and scientific associations, methods for distributing medical guidelines, systems for connecting GPs to the hospital specialist, etc. The targets within the MICTRID concept relate to the need to acquire updated knowledge on recent advances in Medical Informatics and Telemedicine.

3. The Research Scenario

The research scenario has, of course, been influenced by the described educational framework. The Biomedical Engineering stream has inspired the construction of the “Politecnico Biosignals Archives” described here below, now available both on CD-ROM and at http://www.cilea.it. Later, interest focused increasingly on advanced clinical databases and on features such as the integration of data and images, and the temporal characteristics of data. Most of the research is included in the activities program of the Centro di Ingegneria Biomedica, a cooperative center of the Italian National Research Council with the Politecnico di Milano, now chaired by Ferdinando Grandori and located at the Dipartimento di Bioingegneria, described at http://www.bioimed.polimi.it.

3.1 Recent Research Activities

3.1.1 Textual and image data integration - ARCADIA

Use of database techniques to store medical records has existed for more than forty years; however, some aspects remain unresolved. This includes management of textual data and image data within a single database. Object-oriented techniques applied to a database management system (DBMS) allow the definition of suitable data structures (e.g. to store digital images): some facilities allow the use of predefined structures when defining new ones. Currently available object-oriented DBMS, however, still have to be improved, both in the schema update and in the query facilities. We

developed a prototype of a medical record which includes some multimedia features, managing both textual and image data. The prototype considers data from the medical records of patients subjected to percutaneous transluminal coronary artery angioplasty (PTCA). We developed it on a Sun workstation with Unix operating system and ONTOS™ as an object-oriented DBMS. The prototype has been named ARCADIA (A Realization of a coronary-artery Angioplasty Data and Image Administrator).

3.1.2 A temporal data model for clinical data
A time-Oriented Medical Record is a medical record based on a temporal data model. In both the clinical and research field there is a need for managing temporal aspects of data in a more functional and complete way in order to satisfy particular needs of that application field. The model we developed has been applied to data from patients who undergo coronary artery angioplasty. These patients, after a 2-3 day hospitalization, undergo periodic follow-ups aimed at verifying the efficacy of angioplasty. Management of temporal aspects of this data is therefore relevant. The temporal data model has been implemented by means of an Object-Oriented Database Management System (OODBMS). Descriptions of the model and of some temporal queries which have been made available by the implementation of this model are provided.

3.1.3 Window-based object-oriented user interface
After designing the temporal data model, which has the ability to manage different time granularities of the clinical information, we focused our attention on designing a window-based user interface. We designed a window-objects hierarchy for the management of data related to PTCA patients. The user interface allows the user to:
- display, enter and modify the clinical data of PTCA patients
- manage more effectively temporal clinical data having different time granularities; more particularly, the user-interface software is able to graphically represent temporal data having different granularities
- manage more effectively textual and image data and their relationships.

3.1.4 Temporal object SQL
After developing the temporal clinical data model, we are designing a Temporal Object SQL. The Temporal Object SQL relies on the non-interactive version of OSQL of ONTOS to make queries on temporal data having different time granularities (i.e. time units). Our temporal SQL uses a three-valued logic (true, false, undefined) in order to manage the uncertainty coming from relationships between temporal data at different granularities. The temporal SQL has been implemented by C++ and ONTOS.

We are strengthening the integration between textual and image data into a database. In particular, we are designing a system which is able to integrate more image data coming from different sources: angiographic images having heterogeneous clinical contents, image sequences, echocardiographic images, and images coming from nuclear medicine. We are also making efforts toward integrating textual, image and graphical data to allow a deeper analysis of the collected data.

3.1.5 Angiocardiographic image compression
We defined and implemented three new irreversible compression techniques for digital angio-cardiographic static images: Brightness Error Limitation (BEL), Pseudo-gradient Adaptive Brightness Error Limitation (PABEL), Pseudo-gradient Adaptive Brightness and Contrast Error Limitation (PABEL). To scan digital images we implemented an algorithm based on the Peano-Hilbert plane-filling curve. We applied our compression techniques to 168 static images selected from angiographic 35 mm films. We achieved best compression results applying the PACB method, obtaining a mean compression ratio of about 8:1. Consulted cardiologists did not find significant diagnostic differences between original images and reconstructed ones.

3.2 Long-term Research Activities

3.2.1 Normal subjects ECG-and-respiration reference databases on CD-ROM
A number of new quantifiers recently suggested for clinical practice and already provided by some monitoring instruments are considered to be insufficiently tested on the normal population. The CD-ROM based technology allows the construction of easy-to-use dynamic archives of biosignals and bioimages. They can give truly positive contributions to the needed testing procedures. This situation refers to the validation of computer algorithms for ECG analysis. We built the Politecnico of Granda VCG/ECG Database on Young Normal Subject. It was developed to investigate uneventful ECG variability. It consists of 23 recordings about 30 minutes long, from 23 young normal subjects. Recordings consist of the three orthogonal ECG leads corrected according to Frank. A concerted effort was made to ensure maximum fidelity of recordings. Main technical features are: sampling frequency of 500 Hz, resolution of 2.4 units on 12 bits. The second database is the Poli/Medlav Database on ECG...
and-Respiration, developed to investigate interaction among cardio and respiratory systems. It consists of 20 recordings, about 23 minutes long, from 20 young normal subjects. Recording consists of three ECG leads (the three orthogonal leads corrected according to Frank), and two respiratory traces: the respired airflow and the body volume variations, both measured with a plethysmographic chamber. Main technical features are sampling frequency of 500 Hz, ECG resolution of 2.4 μV/unit, respiration resolution of about 0.125 mm/s/unit, both on 12 bits. Data format respects the practical standards used for similar applications in recent years.

3.2.2 The DEKG software

One question to be answered by any teacher relates to ways to help students when they make mistakes. To give such help in the field of teaching dynamic electrocardiography, we built up an effective integration of two CAI tools that we have developed in recent years. The first CAI tool is the DEKG-Trainer system, an instructional aid oriented towards environmental simulation and summative evaluation in the field of dynamic electrocardiography teaching. The second CAI tool is the Clinic Arrhythmia Database - a database which holds a teaching-oriented version of the arrhythmia knowledge. The integration we have implemented is the DEKG-Manager system. It provides a formative evaluation of a student who has made classification mistakes. The DEKG-Manager intends, therefore, to correct the erroneous beliefs which could have driven the student to formulate a wrong diagnosis. The system has two working modes. The first mode is dedicated to formative evaluation. When the student classifies a heart beat in a wrong way using the DEKG-Trainer, our system allows the student to compare the morphological characteristics of the beat really present in the tracing with those pertaining to the erroneous diagnosis, highlighting the difference between the two descriptions. The student can also examine the segment of tracing related to a beat classified in a wrong way and analyze the classes of rhythms compatible with the class of the current beat. The second mode consists in the query of the Clinic Arrhythmia Database. In this case, the student can freely compare the different descriptions contained in the classes of beats present in the database and examine the rhythms compatible with them. The descriptive information obtained from the Clinic Arrhythmia Database is displayed within a graphical schema similar to the Entity-Relationship model. Graphical symbols and colors are used to underline a different degree of importance of the morphological attributes typical of each considered diagnostic class. Finally, the DEKG-Manager system, though not all-encompassing, intends to be an effective and easy-to-use aid to a student who wants to fill the gaps in his knowledge of dynamic electrocardiography.

3.2.3 The MSx2 software (Multi-Service Medical Software)

Many clinics are interested in using software packages in daily practice. Such packages, however, if not integrated are seriously limited in their scope. This means that their daily use requires switching from one program to another and, at times, interrupting the running of an individual program. A multi-task approach would not solve the common problem with separate packages, as it does not dispense with the need to input the same data repeatedly. We developed a Multi-Service Medical Software package (MSx2), which was also developed as an example of practical integration of some clinically relevant functions. The package runs on a PC in an MS-DOS environment and integrates a time-oriented medical record management unit (TOMRU) and a drug information management unit (DIMU). TOMRU handles the follow-up data of ambulatory patients. DIMU performs a drug-information reference service as concerns posology, content, effects and possible interactions. Of the possible database configurations allowed by MSx2, the cardiology patient database (MSx2/C) and hypertensive patient database (MSx2/H) were developed. Configuring MSx2 should in any case be left to an expert user, in charge of database management. The clinical information to be included in the configurations was obtained by discussing the needs of and obtaining the consensus of clinical practitioners. MSx2/C was handed over to hundreds of clinical centers during the computerized itinerant courses held to train would-be users. MSx2 can easily transfer patient data to statistical processing packages.

3.2.4 Self-monitoring of paroxysmal atrial fibrillation in ambulatory patients

Paroxysmal Atrial Fibrillation (PAF) is a typical cardiac pathology where both Holter monitoring and traditional ECG are inadequate instrumentation systems. Probability to record PAF events - symptomatic episodes occurring in unpredictable moments - with 24 hours recording is low. Production of an objective instrumental documentation based on ECG for ambulatory patients is still a problem. Documentation might be obtained with a portable instrument given to the patient for self-documentation of pathological events. The device must permit many hours of active recording, even if it stays on standby for months. This is allowed by the Paroxysmal Atrial Fibrillation Histogram-based Portable Identifier (PAFHIPI) which we have built. The PAFHIPI is a low-cost and easy-to-use portable solid-state recorder. The method used to investigate atrial fibrillation events is based...
on morphology of some histograms: the first based on RR intervals values series and the second based on one of time.

3.2.5 Public-domain medical software evaluation

A vast quantity of public-domain medical software is available. Therefore we developed a classification scheme that includes identification data (e.g., name of the software, author...), description (hardware and software requirements), classification (software category, application domain...) and evaluation data (external and internal quality factors, according to software engineering criteria). We tested the scheme on the public-domain software available at the SCAMC® meetings (about 36 Mbytes). The software was classified by employing students from a medical informatics Masters' course in computer science; the information collected was stored in a database we developed with Paradox.

3.2.6 Riva-Rocci & Poli-Mi

For non-invasive measurement of systolic and diastolic blood pressures values, some instruments allow recording of complete pressure signals. Recent advances in biomedical signal processing have suggested new methods for deeper investigation of such signals, both in the time and the frequency domain. The Riva-Rocci & Poli-Mi Signal Base Management System is a software package that is easily used by physicians for testing these methods in different pathophysiological conditions on a large-scale basis.

4. The “Visible Human Dataset - Milano Mirror Site”

The Visible Human Dataset (VHD) is the largest atlas of multimodal digital bioimages of the human body. A product of the National Library of Medicine in Bethesda, it consists of about 20,000 images from selected horizontal sections of the male and the female body. Besides photographic images, there are MRI and CT images. The VHD includes presentation of transverse, sagittal and oblique cross-sectional images of the body, as well as illustrating extraction of organs and three-dimensional detailed models of the human anatomy. All this is the basis for the construction of interactive simulators, to be used as a teaching aid in Medicine. The First International Conference on the Visible Human Project was held at the National Library of Medicine in Bethesda in October 1996.

The Cilea-MediSan section of the Cilea University Consortium for Information and Communication Technology and the Politecnico di Milano have investigated the difficulties in using 56 Gigabytes of data via Internet from the Continental Europe through transatlantic connections. Thus, the Politecnico di Milano and the Cilea have combined their technology and capacity to open the Milano Mirror Site of the VHD. This is intended to offer a high-level function to users of the Continental Europe, provided they are licensed by the National Library of Medicine to use the VHD data. Thanks to the sponsorships of four companies (Bracco, Imation, Hewlett-Packard and Telecom Italia) the “Visible Human Dataset - Milano Mirror Site”® opened its service to the Continental Europe at the http://vhd-mms.cilea.it on February 1997 and became fully operational in July 1997. The services, based on the new hardware, include FTP and other functions.

5. Concluding Remarks

The educational and research activities in Medical Informatics and Telemedicine described here are also available at http://www.medinfopoli.polimi.it.
